Data Structures &

Advanced Programming

Ordered Structures

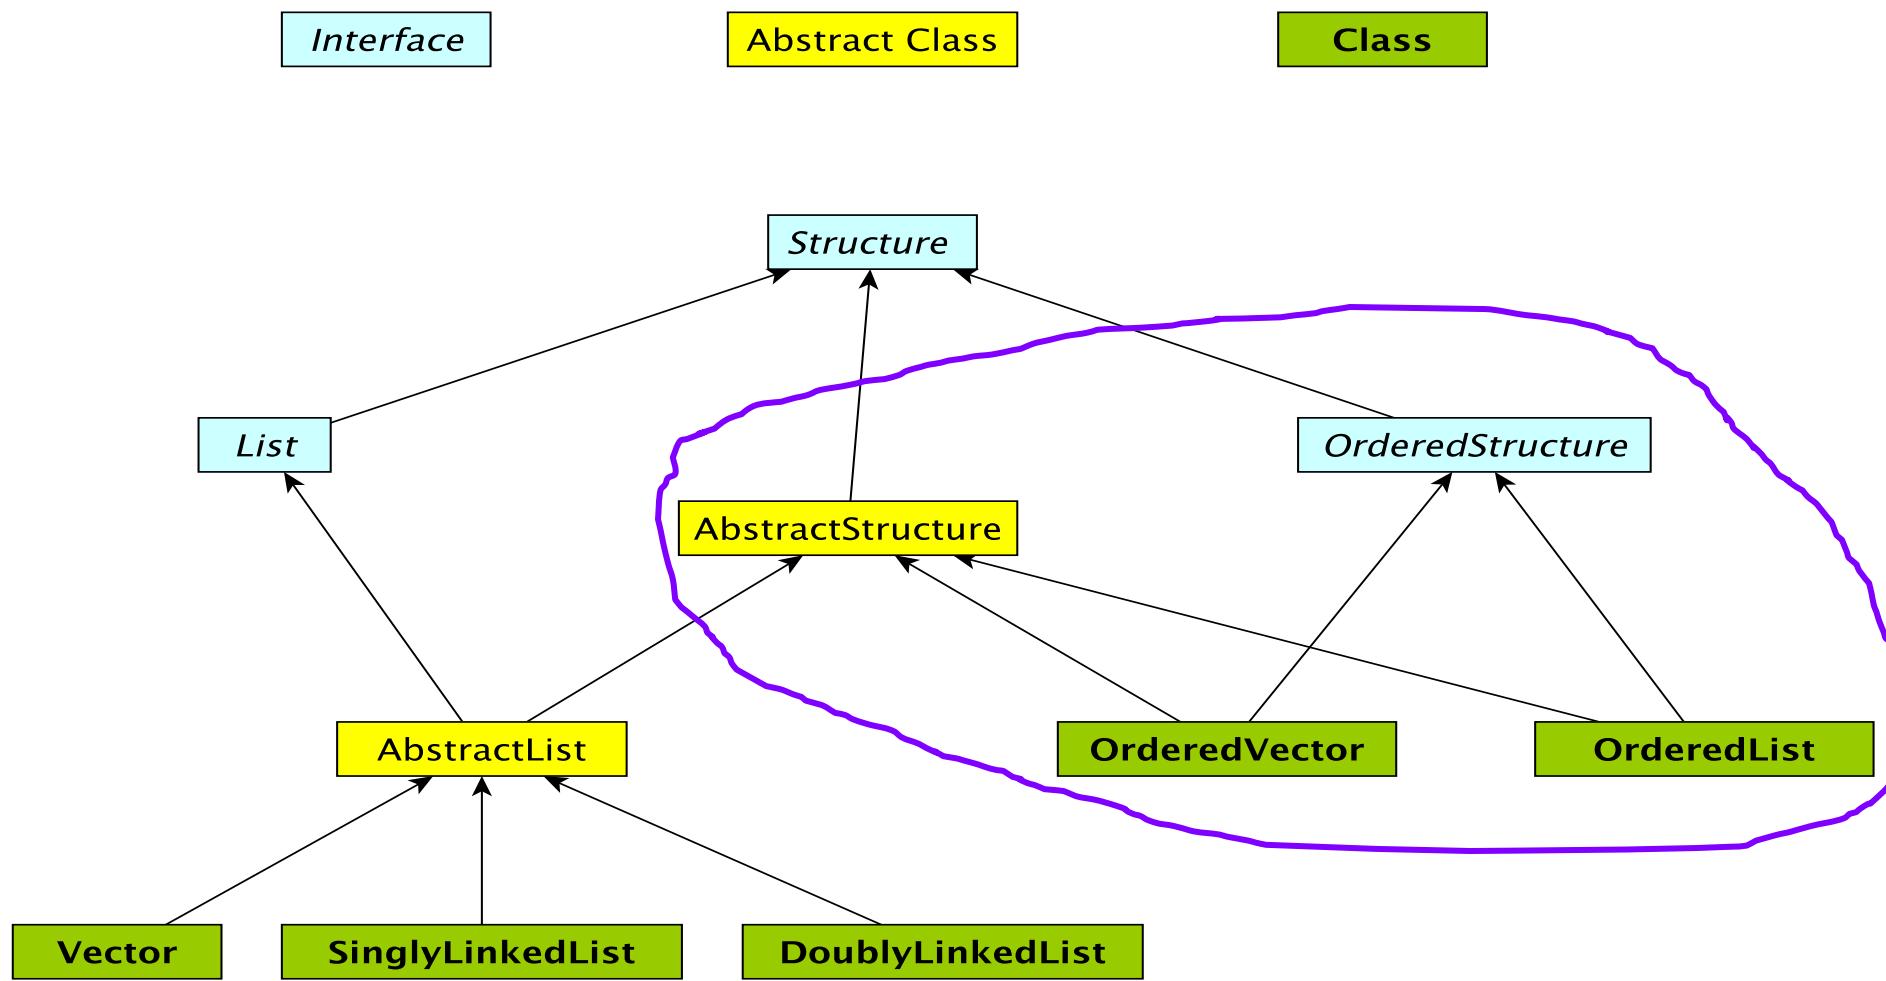

Ordered Structures

Ordered Structures

- Until now, we have not required a specific ordering to the data stored in our structures
 - If we wanted the data ordered/sorted, we had to do it ourselves
- We often want to keep data ordered
 - Allows for faster searching
 - Easier data mining - easy to find best, worst, and median values, as well as rank (relative position)

The Structure Hierarchy

(partial view)

Ordering Structures

- The key to establishing order is being able to compare objects
- We already know how to compare two objects...how?
- Comparators and `compare(T a, T b)`
- Comparable interface and `compareTo(T that)`
- Two means to an end: which should we use?

BOTH!

Ordered Vectors

- We want to create a Vector that is always sorted
 - When new elements are added, they are inserted into correct position
 - We still want many of the standard set of Vector methods
 - add, remove, contains, size, iterator, ...
 - But not all!
 - `set(l, value)` would be a problem!
- Two choices : Extend Vector or Contain a Vector
 - We choose: Contain a Vector
 - Allows for more focused interface
 - Avoid corrupting order by controlled access to Vector
- We will implement a new class (`OrderedVector`)
 - Start with Comparable
 - Generalize to use Comparator instead of Comparable

OrderedVector Methods

```
public class OrderedVector<E extends Comparable<E>>
    implements OrderedStructure<E> {
    protected Vector<E> data;

    public OrderedVector() {
        data = new Vector<E>();
    }

    public void add(E value) {
        int pos = locate(value);
        data.add(pos, value);
    }
}
```

What does locate do?

- **Uses binary search to find either**
 - Location of value if value is in Vector, or
 - Location where value should be added
- **uses iterative version of modified binary search**

Binary Search in Sorted Array

Let's picture the idea: Search for 12

Notes

- Need to keep track of current *search range*: low..high
- Need to know when search has failed
 - Search for 11 : Same sequence until failure

OrderedVector Methods

```
protected int locate(E target) {  
  
    Comparable<E> midValue;  
  
    int low = 0;                                // lowest location  
    int high = data.size();                      // highest location  
    int mid = (low + high)/2;                    // low <= mid <= high  
  
    while (low < high) {  
        midValue = data.get(mid);  
  
        if (midValue.compareTo(target) < 0) low = mid+1;  
        else high = mid;  
  
        mid = (low+high)/2;                      // NB: 0 ≤ mid ≤ data.size()  
    }  
    return low;  
}
```

OrderedVector Methods

```
public boolean contains(E value) {  
    int pos = locate(value);  
    return pos < size() && data.get(pos).equals(value);  
}  
  
public Object remove (E value) {  
    if (contains(value)) {  
        int pos = locate(value);  
        return data.remove(pos);  
    }  
    else return null;  
}
```

Performance:

locate - $O(\log n)$

add - $O(n)$

contains - $O(\log n)$

remove - $O(n)$

Adding Flexibility with Comparators

- We would like to be able to customize the ordering of our ordered structures
- Idea: Add constructor that has a Comparator parameter
- Q: How does structure know whether to use the Comparator or the Comparable ordering?
- A: The NaturalComparator class....

An Aside: Natural Comparators

- NaturalComparators bridge the gap between Comparators and Comparables

```
class NaturalComparator<E extends Comparable<E>>
implements Comparator<E> {
    public int compare(E a, E b) {
        return a.compareTo(b);
    }
}
```

Generalizing OrderedVector

```
public class OrderedVector<E extends Comparable<E>>
    implements OrderedStructure<E> {
    protected Vector<E> data;
    protected Comparator<E> comp;

    public OrderedVector() {
        data = new Vector<E>();
        this.comp = new NaturalComparator<E>();
    }

    public OrderedVector(Comparator<E> comp) {
        data = new Vector<E>();
        this.comp = comp;
    }

    protected int locate(E value) {
        //use modified binary search to find position of value
        //return position
        //use comp.compare instead of compareTo
    }

    //rest stays same...
```

A Confession

- The previous slide demonstrated how to add flexibility to the `OrderedVector` class using Comparators
- Structure5 did not implement this use of Comparators for the `OrderedVector` class!
- But did implement it for `OrderedList`!
- Let's take a look....

Ordered Lists

- Similar to OrderedVector
- Can't efficiently use SinglyLinkedList like OrderedVector used Vector
 - Most methods would traverse list multiple times
- So, we just build a SinglyLinkedList-like structure
- add, contains, remove runtime?
 - All $O(n)$: Must traverse list
- Let's look at a few details....

OrderedList Methods

```
public class OrderedDict<E extends Comparable<E>>
    extends AbstractStructure<E> implements
        OrderedStructure<E> {

    protected Node<E> data; // smallest value
    protected int count;    // size of list
    protected Comparator<? super E> ordering;

    public OrderedDict() {
        this(new NaturalComparator<E>());
    }

    public OrderedDict(Comparator<? super E> ordering) {
        this.ordering = ordering;
        clear();
    }

    public void add(E e) {
        if (data == null) {
            data = new Node<E>(e);
            count = 1;
        } else if (ordering.compare(e, data.data) <= 0) {
            data.insert(e);
        } else {
            Node<E> current = data;
            while (current.next != null && ordering.compare(e, current.next.data) > 0) {
                current = current.next;
            }
            current.insert(e);
        }
        count++;
    }

    public void remove(E e) {
        if (data == null) {
            throw new NoSuchElementException("remove from empty list");
        } else if (data.data.equals(e)) {
            data = data.next;
            count--;
        } else {
            Node<E> current = data;
            while (current.next != null && !current.next.data.equals(e)) {
                current = current.next;
            }
            if (current.next != null) {
                current.next = current.next.next;
                count--;
            }
        }
    }

    public void clear() {
        data = null;
        count = 0;
    }

    public int size() {
        return count;
    }

    public E get(int index) {
        if (index < 0 || index > count - 1) {
            throw new IndexOutOfBoundsException("get index " + index);
        }
        Node<E> current = data;
        for (int i = 0; i < index; i++) {
            current = current.next;
        }
        return current.data;
    }

    public void set(int index, E e) {
        if (index < 0 || index > count - 1) {
            throw new IndexOutOfBoundsException("set index " + index);
        }
        Node<E> current = data;
        for (int i = 0; i < index; i++) {
            current = current.next;
        }
        current.data = e;
    }

    public void sort() {
        if (count > 1) {
            Node<E> current = data;
            while (current != null) {
                Node<E> next = current.next;
                current.next = null;
                insert(current.data);
                current = next;
            }
        }
    }

    private void insert(E e) {
        if (data == null) {
            data = new Node<E>(e);
        } else if (ordering.compare(e, data.data) <= 0) {
            data.insert(e);
        } else {
            Node<E> current = data;
            while (current.next != null && ordering.compare(e, current.next.data) > 0) {
                current = current.next;
            }
            current.insert(e);
        }
    }

    private void print() {
        Node<E> current = data;
        while (current != null) {
            System.out.print(current.data + " ");
            current = current.next;
        }
        System.out.println();
    }
}
```

OrderedList Methods

```
public void clear() {  
    data = null;  
    count = 0;  
}  
  
public boolean contains(E value) {  
    Node<E> finger = data; // target  
  
    while ((finger != null) &&  
           ordering.compare(finger.value(), value) < 0)  
  
        finger = finger.next();  
  
    return finger!=null && value.equals(finger.value());  
}
```

What Could Go Wrong?

OrderedVector

Students

Duane

4.0

Jeannie

3.5

Bill

3.3

- Students compared to each other by GPA
- Suppose next semester I get a 3.7 and Jeannie gets a 3.3

What's the problem?

- We have to recompute GPAs each semester
- What happens if the values are allowed to change?
- We may need to resort vector
 - But since this isn't part of the interface, it may be forgotten
- Options:
 - Avoid changing values in OrderedStructures
 - Incorporate an update method that repositions element
 - Incorporate a resort method
 - This invites adding a “setComparator” method....
 - Always update a value by removing and re-adding

Bonus : Type Safety & Generics

- Question: Since String extends Object, does List<String> extend List<Object>?

- I.e., can I say List<Object> = new List<String>()?

- No. It would compromise the type system:

```
List<String> slist = new List<String>();  
List<Object> olist = slist;      // If this were possible  
olist.add(new Object());        // This would be bad!
```

- It generates a compiler error.

- On the other hand...

```
String[ ] sa = {"I", "love", "java", "!"};  
Object[ ] oa = sa;  
oa[1] = new Object(); // This would be bad!
```

- ...actually compiles

- But causes a run-time error!

Summary & Observations

- Imposing order on the elements in a structure can improve performance of order-related queries.
 - A sorted Vector improves search from $\Theta(n)$ to $\Theta(\log n)$
 - Didn't improve search for linked list, but...
- Consider the *Rank Problem*: Given a collection of comparable objects, find the k^{th} smallest (or k^{th} largest) object in the collection.
 - How would you do this with an ordered linked list?
 - How would you do this with an *unordered* linked list?!
- Using Comparators allows ordered structures to order the same data in a variety of ways.
 - Especially if the Comparator can be replaced!
